Preface

Overview

This article introduces the Linux SPI driver principle and basic debugging methods.

Product Version

Chipset	Kernel Version
All chips develop in linux4.4	Linux 4.4
All chips develop in linux4.19 and above	Linux 4.19 and above

Intended Audience

This document (this guide) is mainly intended for:

Technical support engineers
Software development engineers

Revision History

Version	Author	Date	Change Description
V1.0.0	Huibin Hong	2016-06-29	Initial version
V2.0.0	Dingqiang Lin	2019-12-09	Support Linux 4.19
V2.1.0	Dingqiang Lin	2020-02-13	Adjust SPI slave configuration
V2.2.0	Dingqiang Lin	2020-07-14	Linux 4.19 DTS configuration change, Optimize document layout
V2.3.0	Dingqiang Lin	2020-11-02	Add comment for supporting spi-bus cs-gpios property
V2.3.1	Dingqiang Lin	2020-12-11	Update Linux 4.4 SPI slave description
V2.3.2	Dingqiang Lin	2021-07-06	Add more add configuration description、Add more cs-gpios description
V2.4.0	Dingqiang Lin	2021-08-31	Add FAQs and reduce redundant configurations
V2.5.0	Dingqiang Lin	2021-12-27	Support Linux 5.10

Contents

1. Feature of Rockchip SPI

The serial peripheral interface is called SPI, the following are some of the features supported by the Linux 4.4 SPI driver:

- Motorola SPI protocol is used by default
- Supports 8-bit and 16-bit
- Software programmable clock frequency and transfer rate up to 50MHz
- Support 4 transfer mode configurations of SPI
- One or two chips selects per SPI controller

the following are some of the new features supported by the Linux 4.19 SPI driver:

- Support both slave and master mode

2. Kernel Software

2.1 Code Path

```
drivers/spi/spi.c               /* SPI Driver framework */
drivers/spi/spi-rockchip.c      /* RK SPI  implement of interface */
drivers/spi/spidev.c            /* Create  SPI  device node for using */
drivers/spi/spi-rockchip-test.c /* SPI test driver, it needs to add to Makefile
compiler manually. */
Documentation/spi/spidev_test.c /* SPI test tool in user state */
```

2.2 SPI Device Configuration: RK SPI As Master Port

Kernel Configuration

```
Device Drivers  --->
    [*] SPI support  --->
        <*>   Rockchip SPI controller driver
```

DTS Node Configuration

```
&spi1 {                                 //Quote SPI controller node
    status = "okay";
    //assigned-clock-rates = <200000000>;             //Not configured by
default, the corresponding clock completes the assignment when parsing DTS
    dma-names = "tx","rx";              //Enable DMA mode, it is not recommended
if the general communication byte is less than 32 bytes, set the null assignment
to remove the enable, such as "dma-names;";
```

```
    //rx-sample-delay-ns = <10>;         //Not configured by default, Read
sampling delay. Please refer to "FAQ" and "Delay sampling clock configuration"
for details

    spi_test@10 {
        compatible ="rockchip,spi_test_bus1_cs0";   //The name corresponding to
the driver
        reg = <0>;                        //Chip select 0 or 1
        spi-cpha;                         //If configure it, cpha is 1
        spi-cpol;                         //If configure it,cpol is 1, the clk pin
remains high level.
        spi-lsb-first;                    //IO firstly transfer lsb
        status = "okay";                  //Enable device node
        spi-max-frequency = <24000000>;  //This is clock frequency of SPI clk
output,witch does not exceed 50M.
    };
};
```

Configuration instructions for spiclk assigned-clock-rates and spi-max-frequency:

- spi-max-frequency is the output clock of SPI. spi-max-frequency is output after internal frequency division of SPI working clock spiclk in assigned-clock-rates. Since there are at least 2 internal frequency divisions, the relationship is that SPI assigned clock rates > = 2 * SPI Max frequency;
- Assume that we want 50MHz SPI IO rate，the configuration can be set as: spiclk assigned-clock-rates = <100000000>，spi-max-frequency = <50000000>.
- spiclk assigned-clock-rates should not be lower than 24M, otherwise there may be problems.
- If you need to configure spi-cpha, spiclk assigned-clock-rates <= 6M, 1M <= spi-max-frequency >= 3M.

2.3 SPI Device Configuration: RK SPI As Slave Port

The interfaces "spi_read" and "spi_write" of SPI slave are the same as SPI master.

2.3.1 Configuration of Linux 4.4

Kernel Patch

please check if your code contains the following patches, if not, please add the patch:

*/
        int                     irq;
        void                    *controller_state;
        void                    *controller_data;
```

DTS configuration：

```
&spi0 {
    assigned-clocks = <&pmucru CLK_SPI0>;           //To specify SPI SCLK, you
can view the clock named spiclk in dtsi
    assigned-clock-rates = <200000000>;             //The corresponding clock
completes the assignment when parsing DTS
    spi_test@01 {
        compatible = "rockchip,spi_test_bus0_cs1";
        id = <1>;
        reg = <1>;
        //spi-max-frequency = <24000000>; is no need
        spi-slave-mode;      //if enble slave mode,just modify here
    };
};
```

Note:

1. The working clock must be more than 6 times of the IO clock sent by the master. For example, if the assigned-clock-rates are < 48000000 >, then the clock sent by the master must be less than 8MHz
2. The Linux 4.4 framework does not make special optimization for SPI slave, so there are two kinds of transmission states:
    1. DMA transmission: after transmission initiation, the process enters the timeout mechanism of waiting for completion, and the DMA names of DMA transmission can be closed by adjusting "DMA names;" by DTS
    2. CPU transmission: while waits for the transmission to complete in the underlying driver, and CPU is busy
3. Using RK SPI as a slave, you can consider the following scenarios:
    1. Turn off DMA and block transmission only with CPU
    2. If the transmission is set to be greater than 32 bytes, DMA transmission is used, and the transmission waiting for completion timeout mechanism
    3. A GPIO is added between the master and slave devices, and the master device outputs the message to the slave device to transfer ready to reduce the CPU busy waiting time

2.3.2 Configuration of Linux 4.19 and above

Kernel Configuration

```
Device Drivers  --->
    [*] SPI support  --->
        [*]   SPI slave protocol handlers
```

DTS configuration

```
&spi1 {
    status = "okay";
    dma-names = "tx","rx";
    spi-slave;                                          //enable slave mode
    slave {                                             //As spi-bus requied,
SPI slave sub-node should name start with "slave"
        compatible ="rockchip,spi_test_bus1_cs0";
        reg = <0>;
        id = <0>;
    };
};
```

Note:

- In the actual use scenario, we can consider adding a GPIO between the master and the slave, and the master device outputs to notify the slave device to transfer ready to reduce the CPU busy waiting time

2.3.3 Tips for SPI slave test

If SPI working as slave, you must start" slave read" and then start "master write". Otherwise, the slave will not finish reading and the master has finished writing.

If it is slave write , then master read, also needs to start slave write first, because only slave sends clock, slave will work, and master will sent or received data immediately.

Based on the third chapter:

First slave: `echo write 0 1 16 > /dev/spi_misc_test`

Then master: `echo read 0 1 16 > /dev/spi_misc_test`

2.4 SPI Device Driver

Register device driver:

```
#include <linux/init.h>
#include <linux/module.h>
#include <linux/platform_device.h>
#include <linux/of.h>
#include <linux/spi/spi.h>

static int spi_test_probe(struct spi_device *spi)
{
    int ret;

    if(!spi)
        return -ENOMEM;
    spi->bits_per_word= 8;
    ret= spi_setup(spi);
    if(ret < 0) {
        dev_err(&spi->dev,"ERR: fail to setup spi\n");
        return-1;
    }

    return ret;
}

static int spi_test_remove(struct spi_device *spi)
{
    printk("%s\n",__func__);
    return 0;
}

static const struct of_device_id spi_test_dt_match[]= {
    {.compatible = "rockchip,spi_test_bus1_cs0", },
    {.compatible = "rockchip,spi_test_bus1_cs1", },
    {},
};
MODULE_DEVICE_TABLE(of, spi_test_dt_match);

static struct spi_driver spi_test_driver = {
    .driver = {
        .name  = "spi_test",
        .owner = THIS_MODULE,
        .of_match_table = of_match_ptr(spi_test_dt_match),
    },
    .probe = spi_test_probe,
    .remove = spi_test_remove,
};

static int __init spi_test_init(void)
```

```
{
    int ret = 0;
    ret = spi_register_driver(&spi_test_driver);
    return ret;
}
module_init(spi_test_init);

static void __exit spi_test_exit(void)
{
    return spi_unregister_driver(&spi_test_driver);
}
module_exit(spi_test_exit);
```

For SPI read and write operations, please refer to `include/linux/spi/spi.h`.

```
static inline int
spi_write(struct spi_device *spi,const void *buf, size_t len)
static inline int
spi_read(struct spi_device *spi,void *buf, size_t len)
static inline int
spi_write_and_read(structspi_device *spi, const void *tx_buf, void *rx_buf,
size_t len)
```

2.5 User mode SPI device Configuration

User mode SPI device means operating the SPI interface in user space directly, which makes it convenient for many SPI peripheral drivers run in user space.

There is no need to change the kernel to facilitate driver development.

Kernel Configuration

```
Device Drivers  --->
    [*] SPI support  --->
        [*]   User mode SPI device driver support
```

DTS Configuration

```
&spi0 {
    status = "okay";
    max-freq = <50000000>;
    spi_test@00 {
        compatible = "rockchip,spidev";
        reg = <0>;
        spi-max-frequency = <5000000>;
    };
};
```

Using Instruction

After the driver device is successfully registered, a device like this name will be displayed: /dev/spidev1.1

For the demo of spidev operation, please refer to:

- Kernel 4.4 Documentation/spi/spidev_test.c

- Kernel 4.19 and later tools/spi/spidev_test.c
- After the kernel project is compiled, enter the corresponding path and enter the following command to directly compile the standard SPI app program:

```
make CROSS_COMPILE=~/path-to-toolchain/gcc-xxxxx-toolchain/bin/xxxx-linux-gnu-
    # Choose kernel toolchain
```

- It supports the configuration of SPI slave devices. Refer to "SPI Device Configuration: RK SPI As Slave Port", in which the DTS configuration sub node should remain "rockchip, spidev"

2.6 Support cs-gpios

Users can use the cs-gpios attribute of spi-bus to implement gpio simulation cs to extend SPI chip selection signal. Users can refer to the kernel document `Documentation/devicetree/bindings/spi/spi-bus.txt` to learn more about cs-gpios.

2.6.1 Configuration of Linux 4.4

This support needs more support patches. Please contact RK Engineer for the corresponding patches.

2.6.2 Configuration of Linux 4.19 and above

Take spi1_cs2n in GPIO0_C4 for example:

Set the cs-gpio pin and reference it in the SPI node

```

        status = "disabled";
};
```

SPI node reassigns CS pin

```
+&spi1 {
+       status = "okay";
+       max-freq = <48000000>;
+       cs-gpios = <&gpio0 RK_PC2 GPIO_ACTIVE_LOW>, <&gpio0 RK_PC3
GPIO_ACTIVE_LOW>, <&gpio0 RK_PC4 GPIO_ACTIVE_LOW>;
        spi_test@00 {
                compatible = "rockchip,spi_test_bus1_cs0";
...
+       spi_test@02 {
+               compatible = "rockchip,spi_test_bus1_cs2";
+               id = <2>;
+               reg = <0x2>;
+               spi-cpha;
+               spi-cpol;
+               spi-lsb-first;
+               spi-max-frequency = <16000000>;
+       };
};
```

Note:

- If you want to extend cs with gpio, all cs should be converted to gpio function and supported by cs-gpios property.

3. SPI Testing Driver in Kernel

3.1 Code Path

drivers/spi/spi-rockchip-test.c

3.2 SPI Testing Device Configuration

Kernel Path

```
drivers/spi/Makefile
+obj-y                                  += spi-rockchip-test.o
```

DTS Configuraion

```
&spi0 {
    status = "okay";
    spi_test@00 {
        compatible = "rockchip,spi_test_bus0_cs0";
        id = <0>;       //This attribute is used to distinguish different SPI
slave devices in "spi-rockchip-test.c".
        reg = <0>;      //chip select  0:cs0  1:cs1
        spi-max-frequency = <24000000>;                 //spi output clock
    };
    spi_test@01 {
        compatible = "rockchip,spi_test_bus0_cs1";
        id = <1>;
        reg = <1>;
        spi-max-frequency = <24000000>;
    };
};
```

Driver log

```
[    0.457137]
rockchip_spi_test_probe:name=spi_test_bus0_cs0,bus_num=0,cs=0,mode=11,speed=16000
000
[    0.457308]
rockchip_spi_test_probe:name=spi_test_bus0_cs1,bus_num=0,cs=1,mode=11,speed=16000
000
```

3.3 Test Command

```
echo write 0 10 255 > /dev/spi_misc_test
echo write 0 10 255 init.rc > /dev/spi_misc_test
echo read 0 10 255 > /dev/spi_misc_test
echo loop 0 10 255 > /dev/spi_misc_test
echo setspeed 0 1000000 > /dev/spi_misc_test
```

The above means:

Echo type id number of loops transfer length > /dev/spi_misc_test

Echo setspeed id frequency (in Hz) > /dev/spi_misc_test

You can modify the test case by yourself if you want.

4. FAQ

4.1 SPI no signal

- Confirm that the driver is running before debugging
- Ensure that the IOMUX configuration of the SPI 4 pins is correct .
- Confirm that during the TX sending, the TX pin has a normal waveform, CLK has a normal CLOCK signal, and the CS signal is pulled low.
- If the clock frequency is high, considering increasing the drive strength to improve the signal.
- How to simply judge whether SPI DMA is enabled or not? If the serial port printing does not have the following keywords, DMA is enabled successfully:

```
[    0.457137] Failed to request TX DMA channel
[    0.457237] Failed to request RX DMA channel
```

4.2 How to design application code in SPI

Please select the appropriate object function interface before writing the driver.

Custom SPI device driver

Refer to "SPI Device Driver", for example: drivers/spi/spi-rockchip-test.c.

Application program based on spidev standard device node

Refer to "User mode SPI device Configuration"

4.3 Delay sampling clock configuration

In the case of high SPI IO rate, the normal SPI mode may still not match the output delay of external devices, and RK SPI master read may not be able to sample valid data. SPI RSD logic needs to be enabled to delay the sampling clock.

RK SPI RSD (read sample delay) control logic has the following characteristics:

- The assignable values are 0, 1, 2, 3
- The delay unit is 1 spi_clk cycle, i.e. the working clock of the controller, see "SPI Device Configuration" for details

rx-sample-delay actual delay is the RSD effective value closest to the DTS set value, subject to spi_clk 200MHz, cycle 5ns, for example:

The actual configurable delay of RSD is 0, 5ns, 10ns and 15ns. RX sample delay is set to 12ns, which is close to the effective value of 10ns, so the final delay is 10ns.
